(54) Title: POLYOLEFIN BLENDS OF BIMODAL MOLECULAR WEIGHT DISTRIBUTION

(57) Abstract

Resins which are in situ catalytically produced blends of broad bimodal molecular weight distribution ethylene resin are produced. The resins of the invention are characterized by a blend of low molecular weight component and high molecular weight component with a very broad range. The resin has a molecular weight distribution, which is characterized as MFR or M_w/M_n . The bimodal molecular weight resins can be processed into films on existing equipment, and exhibit good processability in blown film production and provide film product of excellent FQR. The resin of the invention exhibits reduced tendency towards die-lip buildup and smoking in on-line operations.

"POLYOLEFIN BLENDS OF BIMODAL MOLECULAR WEIGHT DISTRIBUTION"

5 This invention relates to a catalytically produced blend comprising a high molecular weight component and low molecular weight component. These blends may be characterized as exhibiting bimodal or broad molecular weight distribution. The blend comprises polymers and copolymers of ethylene and
10 admixtures thereof. The catalyst which is used contains two different transition metals. The catalyst allows for the production of the blend in a single reactor. The resulting blends embrace a broad spectrum of product compositions, determined by the weight fractions and molecular weights of the
15 individual components. The blends can be processed into films of excellent appearance, exhibiting very low gel levels.

 Bimodal molecular weight distribution of a resin indicates that a resin comprises two components of different molecular weight, and implicitly requires a relatively higher molecular
20 weight component (HMW) and low molecular weight (LMW) component. Physical blending of two different polymers will produce a bimodal blend. Such a concept appears in US-A-4461873. Those physically produced blends contain high gel levels. Accordingly, their actual application in film production is of
25 theoretical interest only because of film appearance due to those gels.

 To replace physical blending, the art shows a development by which such bimodal resin blends are produced by process techniques, sometimes referenced as tandem process
30 polymerization. Such a process relies on a two (or more) reactor set up; in one reactor, one of the two components of the bimodal blend is produced under a set of conditions maintained in the first reactor, and transferred to a second reactor, where under a different set of conditions from those in the first
35 reactor, the second component is produced, with a different molecular weight. Compared to bimodal HMW-high density polyethylene [HMW HDPE] produced by physical blending, blends

- 2 -

produced in a tandem operation may have relatively improved film appearance. However, the film appearance is dependent on the HMW component being a major component, greater than 50 percent by weight fraction, of the blend. US-A-4307209 discusses some 5 of the constraints on composition which the tandem mode of operation imposes on product because of the presence of gels.

The problems which inhere in tandem produced products, as discussed in US-A-4307209, may be due to a function of particles of product which have varying LMW/HMW ratios. It is difficult 10 to avoid having particles that have not incorporated LMW species, particularly, when the HMW component is produced in the first reactor. This may be due to deactivation of the HMW reactor particles or because of their bypassing the LMW reactor. Such particles with fairly high viscosity appear as gels and 15 would be incorporated (through deformation) only if the bulk matrix viscosity was high enough. The latter requires that the weight fraction of the HMW component be fairly high (greater than 55 percent).

The desirability of bimodal products resides in product 20 strength and processability, which are provided by the individual components of the blend. Processability relates to the capacity of the resin to be used in existing lines efficaciously.

In accordance with the invention, broad, and preferably 25 bimodal molecular weight distribution ethylene resin is produced catalytically; moreover, the catalysis can be conducted in one reactor. As a result of catalysis in a single reactor the product has greatly improved inter particle composition homogeneity. This is because the catalyst itself provides sites 30 for catalysis of each of the LWM and HWM component, in the constant process conditions and environment of one reactor. Since these sites are relatively uniform in concentration in the catalyst particle, the polymerization (or copolymerization) product particles will have substantially constant HMW:LMW 35 ratios.

The resins of the invention are characterized by a chemical blend of low molecular weight component and a high molecular

- 3 -

weight component with the HMW component weight fraction being greater than zero. Generally, the HMW component weight fraction can be controlled within a very broad range. The resin has a molecular weight distribution, which is characterized as MFR or 5 M_w/M_n . MFR is the ratio $I_{2,1}/I_2$ [determined by ASTM 1238]. M_w is weight average molecular weight and M_n is number average molecular weight as determined by Gel Permeation Chromatography (GPC).

According to one aspect of the present invention there is 10 provided a resin composition comprising a polymer of ethylene, copolymer of ethylene or a mixture thereof, the resin having a density of 0.89 to 0.97; has a M_w/M_n of 2.5 to 60, and has a FI of 1 to 100, wherein said resin comprises a blend of 2 components of different, molecular weight wherein one of said 15 two components is a high molecular weight component (HMW) and wherein another of said two components is a low molecular weight component (LMW) with a molecular weight less than that of HMW, the HMW component having a FI of 0.005 to 50 and the LMW component having a MI of 0.1 to 20,000 and a M_w/M_n of 2 to 30, 20 and wherein the M_w and the M_w/M_n of said blend in said particles is substantially constant over said range of weight average particle diameter.

Advantageously the resin is in the form of particles having a weight average particle diameter in the range 0.01 to 0.04 25 inches (0.25 to 1 mm).

Advantageously also, the resin is prepared in a single reactor using a catalyst comprising a metallocene transition metal.

According to another aspect of the invention there is 30 provided a process for preparing a resin as described above, comprising polymerizing ethylene or ethylene and another olefinic material in a single reactor in the presence of a catalyst comprising a metallocene transition metal.

According to another aspect of the invention there is 35 provided a film formed from the resin described above.

According to another aspect of the invention there is provided an article blow molded from the resin described above.

- 4 -

The resins which are (broad) bimodal molecular weight resins can be processed into films on existing equipment, and exhibit good processability, in blown film production and provide film product with a low gel level (excellent FQR). The 5 resin of the invention exhibits reduced tendency towards die-lip buildup and smoking in on-line operations. The resin of the invention exhibits these unexpected advantages over a broader range of HMW/LMW composition than that produced by either physical blends or tandem series reactor technology.

10 The figure is a GPC [gel permeation chromatograph] curve of a resin of the invention.

The resins herein are mainly comprised of ethylene. The resins may be homopolymers, copolymers or admixtures of homopolymers and copolymers. Copolymers of ethylene generally 15 contain at least 70 weight percent ethylene and an alpha olefin of 3 to 10 carbon atoms. Preferred alpha olefins include 1-butene, 1-hexene, 1-octene and 4 methyl-pentene.

The resins produced herein have a specific density in the range of 0.89 to 0.970. The resins which can be produced in 20 accordance with the invention can exhibit densities of high density, medium density or low density resins, respectively. Accordingly, the resins can produced which exhibit specific density in the range of 0.89 to .929 [low density], 0.930 to 0.940 [medium density], and 0.940 to 0.970 [high density]. 25 Preferred resins have a density from 0.930 to 0.970, more preferably 0.940 to 0.970 and most preferably 0.930 to 0.940. An alternative preferred range for density is from 0.918 to 0.929.

The resins of the invention are characterized by a blend 30 of HMW and LMW component with the high molecular weight component weight fraction which is greater than zero. Generally, the HMW component weight fraction can be controlled within a very broad range, while maintaining excellent properties in ultimate applications, such as film production. 35 The weight fraction of HMW component can range from 0.01 to 0.99, preferably from 0.4 to 0.7 and most preferably from 0.5 to 0.6. The resin has a molecular weight distribution, which

- 5 -

is characterized as MFR or M_w/M_n . The MFR of resin products of the invention can range from 20 to 300, preferably from 60 to 200, and most preferably from 80 to 150. The M_w/M_n of resin products of the invention can range from 2.5 to 60, preferably 5 from 10 to 40, and most preferably from 15 to 30.

The MFR of the low molecular weight component of the resin products of the invention can range from 15 to 40, preferably from 15 to 30, and most preferably from 15 to 20. The M_w/M_n of the low molecular weight component of the resin products of the 10 invention can range from 2 to 30, preferably 2 to 5, more preferably from 2 to 3.5, and most preferably from 2 to 2.5.

The low molecular weight component of resin product of the invention is much narrower in molecular weight distribution, than that produced by a conventional Ziegler Natta catalyst 15 containing only one transition metal such as titanium and/or that produced by a conventional tandem two-reactor process. The narrow MWD of the LMW component can be prepared by using a single site metallocene catalyst component. This narrower molecular weight distribution of the low molecular weight 20 component of the resin of the invention may be responsible for the reduced tendency towards die-lip buildup and smoking because of the absence of very low molecular weight tails. That narrower distribution also enables production of much lower molecular weight component, as the LMW component, without 25 encountering the die-lip buildup problem.

The MFR of the high molecular weight component of the resin products of the invention can range from 25 to 90, preferably from 30 to 50, and most preferably from 30 to 40. The M_w/M_n of the high molecular weight component of the resin products of the 30 invention can range from 3 to 30, preferably from 3 to 10, and most preferably from 3 to 6.

The molecular weight of the LMW component as reflected and expressed herein as MI [ASTM D1238 (190°C/2160 g)] can range from 0.1 to 20000, preferably 20 to 20000, more preferably 100 35 to 5000, and most preferably 2000 to 3000. The FI [ASTM D1238 (190°C/21600 g)] of the high molecular weight component can range from 0.005 to 50, preferably from 0.1 to 5 and most

- 6 -

preferably from 0.2 to 1.0.

The resin product of the invention is preferably unsaturated and crosslinkable. The resin product of the invention preferably has an unsaturation measured by IR which 5 ranges from 0.1 to 3.0, generally from 0.20 to 3.0, preferably from 0.2 to 2 and most preferably from 0.4 to 1.5 (unsaturation per 1000 carbon atoms). The high levels of unsaturation allow for facile cross-linking of resin products of the invention.

When blown into films, these resins exhibit unexpected FQR 10 values. FQR is a qualitative ranking of gel level, ranging from 10 to 60, where 10 FQR indicates no gels and 60 FQR indicates an unacceptably high number of gels. As noted below in the Examples, the FQR of resin products of the invention is superior to those of tandem process produced resins. Generally, the FQR 15 is less than 50, usually less than 30, preferably less than 20 and most preferably 10. In addition to excellent FQR values, the products exhibit excellent dart drop impact resistance.

The resin products of the invention can be referred to as 20 in situ catalytically produced blends of bimodal molecular weight distribution. As noted above, the resins are preferably produced by a catalyst which comprises at least one, and preferably two different transition metals. In a preferred embodiment at least one of the transition metals is provided in the form of a metallocene compound. In a preferred embodiment 25 at least one of the transition metals is provided in the form of a metallocene compound of a transition metal zirconium or hafnium.

Accordingly, the resin product of the invention will 30 generally contain 0.01 to 10 ppm, usually 1 to 5 ppm, and more specifically 1 to 3 ppm (weight) of the transition metal (e.g. Hf, Zr, Ti) which is provided in the catalyst as the metallocene. It will contain 1 to 30 ppm titanium, preferably 1 to 20, and more preferably 1 to 10 ppm titanium provided as a non-metallocene or as $TiCl_4$.

35 The preferred catalysts comprise a cocatalyst comprising an aluminum alkyl compound, such as a trialkyl aluminum free of alumoxane, e.g. TMA, and a catalyst precursor comprising a

- 7 -

carrier, an alumoxane, at least one metallocene and a non-metallocene transition metal source.

The carrier material is a solid, particulate, porous, preferably inorganic material, such as an oxide of silicon 5 and/or of aluminum. The carrier material is used in the form of a dry powder having an average particle size of from about 1 micron to about 250 microns, preferably from about 10 microns to about 150 microns. The surface area of the carrier is at least about 3 square meters per gram (m^2/gm), and preferably at 10 least about $50\ m^2/gm$ up to about $350\ m^2/gm$. The carrier material should be dry, that is, free of absorbed water. Drying of the carrier material can be effected by heating at about $100^\circ C$ to about $1000^\circ C$, preferably at about $600^\circ C$. When the carrier is silica, it is heated to at least $200^\circ C$, preferably 15 about $200^\circ C$ to about $850^\circ C$ and most preferably at about $600^\circ C$. The carrier material must have at least some active hydroxyl (OH) groups to produce the catalyst composition used in the invention.

In the most preferred embodiment, the carrier is silica 20 which, prior to the use thereof in the first catalyst synthesis step, has been dehydrated by fluidizing it with nitrogen and heating at about $600^\circ C$ for about 16 hours to achieve a surface hydroxyl group concentration of about 0.7 millimoles per gram (mmols/gm). The silica of the most preferred embodiment is a 25 high surface area, amorphous silica (surface area = $300\ m^2/gm$; pore volume of $1.65\ cm^3/gm$), and it is a material marketed under the tradenames of Davison 952 or Davison 955 by the Davison Chemical Division of W.R. Grace and Company. The silica is in the form of spherical particles, e.g., as obtained by a spray- 30 drying process.

When the catalyst contains two transition metals components, one of which is a metallocene, and one of which is non-metallocene (free of unsubstituted or substituted cyclopentadienyl groups) the impregnation of the alumoxane in 35 accordance with the unique method described above is preferably undertaken after hydroxyl groups of the carrier material are reacted with an organomagnesium compound and the non-metallocene

- 8 -

transition metal compound. In this embodiment, the amount of Al, provided by alumoxane, is sufficient to provide an Al:transition metal (provided by metallocene) mole ratio ranging from 50 to 500, preferably 75 to 150. The carrier material, 5 having said (OH) groups, is slurried in a non-polar solvent and the resulting slurry is contacted with at least one organomagnesium composition having the empirical formula below. The slurry of the carrier material in the solvent is prepared by introducing the carrier into the solvent, preferably while 10 stirring, and heating the mixture to about 25 to about 70°C, preferably to about 40 to about 60°C. Temperatures here are critical with respect to the non-metallocene transition metal which is subsequently added; that is temperatures in this slurry of about 90°C result in deactivation of the transition metal 15 added subsequently. The slurry is then contacted with the aforementioned organomagnesium composition, while the heating is continued at the aforementioned temperature.

The organomagnesium composition has the empirical formula

20 where R and R' are the same or different C₂-C₁₂ alkyl groups, preferably C₄-C₁₀ alkyl groups, more preferably C₄-C₈ normal alkyl groups, and most preferably both R and R' are n-butyl groups, and m and n are each 0, 1 or 2, providing that m + n is equal to the valence of Mg.

25 Suitable non-polar solvents are materials in which all of the reactants used herein, i.e., the organomagnesium composition, and the non-metallocene transition metal compound, are at least partially soluble and which are liquid at reaction temperatures. Preferred non-polar solvents are alkanes, such 30 as isopentane, hexane, n-heptane, octane, nonane, and decane, although a variety of other materials including cycloalkanes, such as cyclohexane, aromatics, such as benzene, toluene and ethylbenzene, may also be employed. The most preferred non-polar solvent is isopentane. Prior to use, the non-polar 35 solvent should be purified, such as by percolation through silica gel and/or molecular sieves, to remove traces of water, oxygen, polar compounds, and other materials capable of

- 9 -

adversely affecting catalyst activity.

In the most preferred embodiment of the synthesis of this catalyst it is important to add only such an amount of the organomagnesium composition that will be deposited - physically 5 or chemically - onto the support since any excess of the organomagnesium composition in the solution may react with other synthesis chemicals and precipitate outside of the support. The carrier drying temperature affects the number of sites on the carrier available for the organomagnesium composition - the 10 higher the drying temperature the lower the number of sites. Thus, the exact molar ratio of the organomagnesium composition to the hydroxyl groups on the carrier will vary and must be determined on a case-by-case basis to assure that only so much 15 of the organomagnesium composition is added to the solution as will be deposited onto the support without leaving any excess of the organomagnesium composition in the solution.

Furthermore, it is believed that the molar amount of the organomagnesium composition deposited onto the support is greater than the molar content of the hydroxyl groups on the 20 support. Thus, the molar ratios given below are intended only as an approximate guideline and the exact amount of the organomagnesium composition in this embodiment must be controlled by the functional limitation discussed above, i.e., it must not be greater than that which can be deposited onto the 25 support. If greater than that amount is added to the solvent, the excess may react with the non-metallocene transition metal compound, thereby forming a precipitate outside of the support which is detrimental in the synthesis of our catalyst and must be avoided. The amount of the organomagnesium composition which 30 is not greater than that deposited onto the support can be determined in any conventional manner, e.g., by adding the organomagnesium composition to the slurry of the carrier in the solvent, while stirring the slurry, until the organomagnesium composition is detected as a solution in the solvent.

35 For example, for the silica carrier heated at about 600°C, the amount of the organomagnesium composition added to the slurry is such that the molar ratio of Mg to the hydroxyl groups

- 10 -

(OH) on the solid carrier is about 0.5:1 to about 4:1, preferably about 0.8:1 to about 3:1, more preferably about 0.9:1 to about 2:1 and most preferably about 1:1. The organomagnesium composition dissolves in the non-polar solvent to form a 5 solution from which the organomagnesium composition is deposited onto the carrier.

It is also possible to add such an amount of the organomagnesium composition which is in excess of that which will be deposited onto the support, and then remove, e.g., by 10 filtration and washing, any excess of the organomagnesium composition. However, this alternative is less desirable than the most preferred embodiment described above.

After the addition of the organomagnesium composition to the slurry is completed, the slurry is contacted with a non-15 metallocene transition metal compound, free of substituted or unsubstituted cyclopentadienyl groups. The slurry temperature must be maintained at about 25 to about 70°C, preferably to about 40 to about 60°C. As noted above, temperatures in this slurry of about 80°C or greater result in deactivation of the 20 non-metallocene transition metal. Suitable non-metallocene transition metal compounds used herein are compounds of metals of Groups IVA, and VA, of the Periodic Chart of the Elements, as published by the Fisher Scientific Company, Catalog No. 5-702-10, 1978, providing that such compounds are soluble in the 25 non-polar solvents. Non-limiting examples of such compounds are titanium and vanadium halides, e.g., titanium tetrachloride, $TiCl_4$, vanadium tetrachloride, VCl_4 , vanadium oxytrichloride, $VOCl_3$, titanium and vanadium alkoxides, wherein the alkoxide moiety has a branched or unbranched alkyl radical of 1 to about 30 20 carbon atoms, preferably 1 to about 6 carbon atoms. The preferred transition metal compounds are titanium compounds, preferably tetravalent titanium compounds. The most preferred titanium compound is titanium tetrachloride. The amount of titanium or vanadium, in non-metallocene form ranges from a 35 Ti/Mg molar ratio of 0.5 to 2.0, preferably from 0.75 to 1.50.

Mixtures of such non-metallocene transition metal compounds may also be used and generally no restrictions are imposed on

- 11 -

the transition metal compounds which may be included. Any transition metal compound that may be used alone may also be used in conjunction with other transition metal compounds.

Incorporation of the alumoxane-metallocene can be directly 5 to this slurry. Alternatively, and in accordance with the unique method of infusion of alumoxane into the pores of the carrier, the carrier slurry can be stripped of solvent, after the addition of the non-metallocene transition metal compound, to form a free-flowing powder. The free flowing powder can then 10 be impregnated by determining the pore volume of the carrier and providing a metallocene-alumoxane solution in a volume equal to or less than that of the pore volume of the carrier, and recovering a dry catalyst precursor. The amount of solution of aluminoxane activated zirconocene is to obviate the formation 15 of a slurry containing the silica supported titanium in the solution of the activated zirconocene; the actual volume of solution (of activated zirconocene) can be 30% greater than the total pore volume of silica supported titanium without slurry formation.

20 The resulting free-flowing powder, referred to herein as a catalyst precursor, is combined with an activator (sometimes referred as a cocatalyst). The activator is a monomeric anhydrous aluminum compound. The aluminum compound can be a trialkylaluminum, dialkylaluminum hydride, dialkylaluminum 25 halide, alkylaluminum dihydride or alkylaluminum dihalide, in which alkyl is 1 to 6 carbon atoms, methyl, ethyl, propyl, isopropyl, butyl, isobutyl, straight and branched pentyl and hexyl groups. Specific examples include triethylaluminum, triisobutylaluminum and trimethylaluminum. The amount of 30 cocatalyst is sufficient to activate the precursor containing the non-metallocene source of transition metal. Practically, the amount of activator (or cocatalyst) ranges from 80 to 800 ppm, preferably from 200 to 300 ppm, based on the ethylene feed. Preferably, trimethylaluminum (TMA) is the cocatalyst or 35 activator. The amount of the TMA activator is sufficient to give an Al:Ti₂ molar ratio of about 10:1 to about 1000:1, preferably about 15:1 to about 300:1, and most preferably about

- 12 -

20:1 to about 100:1. The catalyst exhibits high activity for long periods of time and exhibits little deactivation.

In a preferred embodiment, the metallocene is added to a solution of the alumoxane prior to impregnating the non-
5 metallocene transition metal supported carrier with the solution. The class of alumoxanes comprises oligomeric linear and/or cyclic alkylalumoxanes represented by the formula:

$R-(Al(R)-O)_n-AlR_2$ for oligomeric, linear alumoxanes and
 $(-Al(R)-O-)_m$ for oligomeric cyclic alumoxane

10 wherein n is 1-40, preferably 10-20, m is 3-40, preferably 3-20 and R is a C_1-C_8 alkyl group and preferably methyl (MAO). It is a mixture of oligomers with a very wide distribution of molecular weights and usually with an average molecular weight of about 1200. MAO is typically kept in solution in toluene.
15 While the MAO solutions remain liquid at fluid bed reactor temperatures, the MAO itself is a solid in the absence of toluene.

Again the maximum volume of the alumoxane solution also including the metallocene is the total pore volume of the 20 carrier material sample. That maximum volume of the alumoxane solution ensures that no slurry of silica is formed. Accordingly, if the pore volume of the carrier material is 1.65 cm^3/g , then the volume of alumoxane will be equal to or less than 1.65 $cm^3/gram$ of carrier material. As a result of this 25 proviso, the impregnated carrier material will appear dry immediately following impregnation although the pores of the carrier will be filled with inter alia solvent. The mole ratio of alumoxane provided aluminum, expressed as Al, to metallocene metal expressed as M (e.g. Zr), ranges from 50 to 500, 30 preferably 75 to 300, and most preferably 100 to 200.

An added advantage of the present invention is that this Al:Zr ratio can be directly controlled. In a preferred embodiment the alumoxane and metallocene compound are mixed together at a temperature of about 20 to 80°C, for 0.1 to 6.0 35 hours, prior to use in the infusion step. The solvent for the metallocene and alumoxane can be appropriate solvents, such as aromatic hydrocarbons, halogenated aromatic hydrocarbons,

- 13 -

ethers, cyclic ethers or esters, preferably it is toluene.

The metallocene compound has the formula $Cp_mMA_nB_p$, in which Cp is an unsubstituted or substituted cyclopentadienyl group, M is zirconium or hafnium and A and B belong to the group 5 including a halogen atom, hydrogen or an alkyl group. In the above formula of the metallocene compound, the preferred transition metal atom M is zirconium. In the above formula of the metallocene compound, the Cp group is an unsubstituted, a mono- or a polysubstituted cyclopentadienyl group. The 10 substituents on the cyclopentadienyl group can be preferably straight-chain C_1-C_6 alkyl groups. The cyclopentadienyl group can be also a part of a bicyclic or a tricyclic moiety such as indenyl, tetrahydroindenyl, fluorenyl or a partially hydrogenated fluorenyl group, as well as a part of a substituted 15 bicyclic or tricyclic moiety. In the case when m in the above formula of the metallocene compound is equal to 2, the cyclopentadienyl groups can be also bridged by polymethylene or dialkylsilane groups, such as $-CH_2-$, $-CH_2-CH_2-$, $-CR'R''-$ and $-CR'R''-CR'R''-$ where R' and R'' are short alkyl groups or hydrogen, 20 $-Si(CH_3)_2-$, $Si(CH_3)_2-CH_2-CH_2-Si(CH_3)_2-$ and similar bridge groups. If the A and B substituents in the above formula of the metallocene compound are halogen atoms, they belong to the group of fluorine, chlorine, bromine or iodine. If the substituents 25 A and B in the above formula of the metallocene compound are alkyl groups, they are preferably straight-chain or branched C_1-C_6 alkyl groups, such as methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, n-pentyl, n-hexyl or n-octyl.

Suitable metallocene compounds include bis(cyclopentadienyl)metal dihalides, bis(cyclopentadienyl)metal 30 hydridohalides, bis(cyclopentadienyl)metal monoalkyl monohalides, bis(cyclopentadienyl)metal dialkyls and bis(indenyl)metal dihalides wherein the metal is zirconium or hafnium, halide groups are preferably chlorine and the alkyl groups are C_1-C_6 alkyls. Illustrative, but non-limiting examples 35 of metallocenes include bis(cyclopentadienyl)zirconium dichloride, bis(cyclopentadienyl)hafnium dichloride, bis(cyclopentadienyl)zirconium dimethyl,

- 14 -

5 bis(cyclopentadienyl)hafnium dimethyl, bis(cyclopentadienyl)zirconium hydridochloride, bis(cyclopentadienyl)hafnium hydridochloride, bis(pentamethylcyclopentadienyl)zirconium dichloride, bis(pentamethylcyclopentadienyl)hafnium dichloride, bis(n-
10 butylcyclopentadienyl)zirconium dichloride, cyclopentadienyl-zirconium trichloride, bis(indenyl)zirconium dichloride, bis(4,5,6,7-tetrahydro-1-indenyl)zirconium dichloride, and ethylene-[bis(4,5,6,7-tetrahydro-1-indenyl)] zirconium dichloride. The metallocene compounds utilized within the embodiment of this art can be used as crystalline solids, as solutions in aromatic hydrocarbons or in a supported form.

15 Solvent may be removed from the alumoxane impregnated pores of the carrier material by heating and/or under a positive pressure induced by an inert gas, such as nitrogen. If employed, the conditions in this step are controlled to reduce, if not to eliminate, agglomeration of impregnated carrier particles and/or crosslinking of the alumoxane. In this step, solvent can be removed by evaporation effected at relatively low
20 elevated temperatures of above about 40°C and below about 50°C to obviate agglomeration of catalyst particles and cross-linking of the alumoxane. Although solvent can be removed by evaporation at relatively higher temperatures than that defined by the range above 40°C and below about 50°C, very short heating
25 times schedules must be employed to obviate agglomeration of catalyst particles and cross-linking of the alumoxane.

POLYMERIZATION

30 The catalyst composition of this invention is preferably used to polymerize either ethylene alone or ethylene in conjunction with higher monomers, such as any one of C₃-C₁₀, more preferably C₄ to C₈, alpha-olefins, e.g., propylene, 1-butene, 1-pentene, 1-hexene, 4-methyl-1-pentene, 1-heptene or 1-octene, preferably 1-butene, 1-pentene, 1-hexene or 4-methyl-1-pentene
35 and most preferably 1-hexene. The polymerization reaction may be carried out using any suitable, conventional olefin polymerization process, such as a slurry, particle form or vapor

- 15 -

phase, e.g., fluid bed reactor, but preferably it is carried out in a vapor phase, fluid bed reactor. The reaction is conducted substantially in the absence of catalyst poisons, such as moisture, carbon monoxide and acetylene, with a catalytically effective amount of the catalyst at a temperature and pressure conditions sufficient to initiate the polymerization reaction. A particularly desirable method for producing polymers according to the present invention is in a fluid bed reactor. Such a reactor and means for operating it are described in US-A-10 4001382, US-A-4302566, and US-A-4481301. The polymer produced in such a reactor contains catalyst particles since the catalyst is not separated from the polymer.

In order to achieve density ranges of about 0.915 to about 0.965 g/cc in the copolymers, it is advisable to copolymerize enough of the C₃ or higher comonomer with ethylene to achieve a level of about 0.1 to about 25 mole percent of the C₃-C₁₀ comonomer in the copolymer. The amount of comonomer needed to achieve this result will depend on the particular comonomer(s) being employed. Further, the various intended comonomers have different reactivity rates, relative to the reactivity rate of ethylene, with respect to the copolymerization thereof with the catalysts of the present invention. Therefore, the amount of comonomer used in the stream of monomers fed to the reactor will also vary depending on the reactivity of the comonomer.

In the most preferred embodiment, the catalyst of the present invention is used to polymerize 1-hexene and ethylene to obtain polymers having the density of about 0.930 to about 0.955 g/cc, and high load melt index (HLMI), I₂₁, values of about 3 to about 12, preferably about 6 to about 8, which are especially suitable for the production of high strength films.

Hydrogen may be used in the polymerization reaction of the present invention in such amounts that the ratio of hydrogen to ethylene is between about 0 to about 2.0 moles of hydrogen per mole of the ethylene monomer in the gas stream. Any gas inert to the catalyst and reactants may also be present in the feed stream.

- 16 -

CONDITIONS IN THE FLUID BED REACTOR FOR THE GAS PHASE POLYMERIZATION AND COPOLYMERIZATION OF ETHYLENE

It is most desirable to operate the fluid bed reactor at a temperature below the sintering temperature of the polymer particles. For the production of ethylene copolymers in the process of the present invention an operating temperature of about 30° to 115°C is preferred, and a temperature of about 75° to 100°C is most preferred. Temperatures of about 70° to 85°C are used to prepare products having a density of about 0.89 to 10 0.930, and temperatures of about 80° to 95°C are used to prepare products having a density of about 0.93 to 0.94, and temperatures of about 90° to 115°C are used to prepare products having a density of about 0.94 to 0.96.

The fluid bed reactor is operated at pressures of up to 15 about 1000 psi (6.9 MPa), and is preferably operated at a pressure of from about 150 to 350 psi (1 MPa to 2.4 MPa), with operation at the higher pressures in such ranges favoring heat transfer since an increase in pressure increases the unit volume heat capacity of the gas.

20 The partially or completely activated catalyst is injected into the bed at a point above the distribution plate at a rate equal to its consumption. Since the catalysts used in the practice of this invention are highly active, injection of the fully activated catalyst into the area below the distribution 25 plate may cause polymerization to begin there and eventually cause plugging of the distribution plate. Injection into the bed, instead, aids in distributing the catalyst throughout the bed and precludes the formation of localized spots of high catalyst concentration.

30 The production rate of polymer in the bed is controlled by the rate of catalyst injection. Since any change in the rate of catalyst injection changes the rate of generation of the heat of reaction, the temperature of the recycle gas is adjusted to accommodate the change in rate of heat generation. Complete 35 instrumentation of both the fluidized bed and the recycle gas cooling system is, of course, necessary to detect any temperature change in the bed so as to enable the operator to

- 17 -

make a suitable adjustment in the temperature of the recycle gas.

Since the rate of heat generation is directly related to product formation, a measurement of the temperature rise of the 5 gas across the reactor (the difference between inlet gas temperature and exit gas temperature) is determinative of the rate of particulate polymer formation at a constant gas velocity.

Under a given set of operating conditions, the fluidized 10 bed is maintained at essentially a constant height by withdrawing a portion of the bed as product at a rate equal to the rate of formation of the particulate polymer product.

The compositions of the invention can be extruded and injection or blow molded into articles or extruded and blown 15 into films. Films can be produced which are 0.2 to 5.0 mils (5 to 127 microns), preferably 0.5 to 2.0 mils (13 to 51 microns), thickness. Blow molded articles include bottles, containers, fuel tanks and drums.

A particularly desirable method for producing linear low 20 density polyethylene polymers according to the present invention is in a single fluid bed reactor unit which is shown and is also described in US-A-4481301.

For film production, the products may contain any of various additives conventionally added to polymer compositions 25 such as lubricants, microtalc, stabilizer, antioxidants, compatibilizers, pigments, etc. These reagents can be employed to stabilize the products against oxidation. For example, additive packages comprising 400-1200 ppm hindered phenol(s); 200-2000 ppm phosphites; 250 to 1000 ppm antistats and 250-2000 30 ppm stearates, for addition to the resin powders, can be used for pelletization. The polymers can be added directly to a blown film extruder, e.g., an Alpine extruder, to produce films having a thickness, for example of about 0.2 to 5 mils (5 to 127 microns).

35 The following Examples further illustrate the essential features of the invention. However, it will be apparent to those skilled in the art that the specific reactants and

- 18 -

reaction conditions used in the Examples do not limit the scope of the invention as claimed.

The properties of the polymers produced in the Examples were determined by the following test methods:

5

Density

ASTM D-1505 - a plaque is made and conditioned for one hour at 100°C to approach equilibrium crystallinity. Measurement for density is then made in a density gradient column; reported as g/cm³.

10

Melt Index
(MI), I₂

ASTM D-1238 - (190°C/2160 g)
Measured at 190°C - reported as grams per 10 minutes.

15

High Load
Melt Index
(HLDI), I₂₁ or FI

ASTM D-1238 - (190°C/21600 g)
Measured at 10 times the weight used in the melt index test above.

EXAMPLES

25 The following examples C and D are in examples of US-A-5332706.

EXAMPLE C

This catalyst was prepared in two stages.

Step I: 495 grams of Davison grade 955 silica, previously 30 calcined with dry nitrogen for about 12 hours at 600°C, was added to a 2 gallon (7.6 litre) stainless steel autoclave under a slow nitrogen purge to eliminate oxygen and moisture from the catalyst preparation vessel. Then, 4.0 liters of dry isopentane (IC5) was added to the autoclave and the silica/IC5 were 35 slurried at about 100 rpm and the internal temperature was maintained at about 55-60°C. Next, 469 ml of a 0.76 molar solution of dibutylmagnesium in heptane was added to the

- 19 -

silica/IC5 slurry and stirring was continued for 60 minutes. Next, 39.1 ml of neat titanium tetrachloride was diluted with about 40 ml of IC5 and this solution was added to the autoclave and stirring was continued for 60 minutes. Finally, the 5 solvents were removed with a nitrogen purge through a vent line and 497 grams of a brown free-flowing powder were obtained. Ti found was 2.62 wt%; Mg found was 1.33 wt% and Ti/Mg molar ratio was 1.0.

Step II: 492 grams of the product of the first stage was 10 added to a 1.6 gallon (6 litre) glass catalyst preparation vessel fitted with a temperature jacket and an internal stirrer. The product of the first stage had an estimated pore volume of 1.5 cc/g (i.e. 738 cc of pore volume). Then into a stainless 15 steel Hoke bomb was added 13.93 grams of $(BuCp)_2ZrCl_2$ (34.4 mmol Zr) and 717.5 ml of a methylalumoxane solution (3,444 mmol of Al) in toluene (4.8 Molar). Note: The total volume of the methylalumoxane/toluene solution is equal to or less than the total pore volume of the product of the first step. Next, the toluene solution containing the methylalumoxane and the 20 zirconium compound were mixed and then the solution was added to the product of the first step in approximately 5 ml aliquots over 90 minutes; (during this time, the product of the first step remains completely dry and always consists of a free-flowing powder). Finally, nitrogen is purged through the glass 25 vessel for about 5 hours with the jacket temperature at about 45°C. Yield: 877 grams of a free-flowing powder. Ti found was 1.85 wt%; Zr found was 0.30 wt%.

EXAMPLE C-1

30 This catalyst was also prepared in a two step process as described in EXAMPLE C. Step I was the same as EXAMPLE C, but in Step II we used 406 grams of reaction product from the first step, 826 mls of methylalumoxane solution and 15.6 grams of $(BuCp)_2ZrCl_2$ were used. Yield: 568 grams of a brown free-flowing powder. Ti found was 1.58 wt% Zr found was 0.45 wt%.

EXAMPLE C-2

This catalyst was also prepared in a two step process as

- 20 -

described in EXAMPLE C. Step II was the same as EXAMPLE C, but in Step II we used 506 grams of reaction product from the first step, 921 mls of methylalumoxane solution and 17.5 grams of (BuCp)₂ZrCl₂ were used. Yield: 866 grams of a brown free-flowing powder. Ti found was 1.64 wt%, Zr found was 0.43 wt%.

5

EXAMPLE D

The catalyst described in Example C was examined in a pilot plant fluid bed gas phase reactor under the following 10 conditions:

15

ethylene partial pressure	180 psi (1.2 MPa)
hydrogen/ethylene	0.005-0.008
hexene/ethylene	0.015
reactor temperature	95°C
TMA	200 ppm

The resin prepared at a productivity of about 1400 g polymer/g catalyst had the following characteristics:

20

average particle size	0.017 inches (0.43 mm)
resin metal (Ti) content	13.0 ppm
HLMI (I ₂₁)	5.3
MFR (I ₂₁ /I ₂)	113
Density	0.949 g/cc

25

Properties of films of the product of Example D are compared to the commercially produced product OxyChem L5005 in the following table.

- 21 -

<u>Sample</u>	<u>Ti/Zr</u>	<u>OxyChem L5005</u>
I ₂₁	5.3	8.0
MFR	113	160
Density	0.949	0.950
5 Throughput, lb/hr	98	120
Melt Pressure (at 120 lb/h), psi	7550	6450
(Melt Pressure at 54 Kg/h), MPa	52	44)
FQR	15	15
Dart Drop, 1 mil. g (0.025 mm g)	565	325
10 0.5 mil. g (0.013 mm g)	410	420
MD Elmendorf Tear, 0.5 mil. g/mil (0.013 mm g/mm)	37	25
	1500	980)

The GPC results show that the Example D bimodal product has
 15 a high molecular weight component with higher molecular weight
 than that produced in the tandem two reactor process. The film
 of Example D is substantially reduced in, if not free of, gel
 content. The film of the Example D product has improved dart
 impact [as measured by dart drop ASTM D1709 (Method A)] and
 20 Elmendorf Tear (ASTM-1992).

EXAMPLE E

A catalyst similar to that described in Example C with a
 higher MAO loading (9.5 mmol Al/g silica at an Al/Zr ratio of
 25 100) was examined in a pilot plant fluid bed gas phase reactor
 under the following conditions:

	ethylene partial pressure	185 psi (1.28 MPa)
	hydrogen/ethylene ratio	0.007
	hexene/ethylene ratio	0.004
30	reactor temperature	95°C
	TMA	263 ppm

The resin prepared had the following characteristics:

35	average particle size	0.017 in. (0.43 mm)
	resin Ti content	12 ppm
	HLMI (I ₂₁)	26 g/10 min

- 22 -

MFR (I_{21}/I_2)	259 g/10 min
Density	0.960 g/cc

Resin was fabricated into 28 g bottles on a reciprocating 5 Improved blow molding machine. Properties of the resin and bottles of the product of Example E are compared to the commercially produced product USI 734 in the following table.

	Invention Product	Commercial Product
10 Sample	Ti/Zr	USI LR734
I_{21}	26	34
MFR	259	110
Density	0.960	0.954
Bent Strip ESCR*, F50, hrs	128	<21
15 (10% Igepal with slit)		
Net Bottle Weight, g	26.3	27.7
Top Pinch Width, in (cm)	2.177 (5.53)	2.188 (5.56)

*Bent Strip ESCR ASTM D-1693

20 The above results show that the invention product has a significantly improved ESCR at higher stiffness (density) compared to a commercial blow molding product at comparable processability (swell characteristics).

25

EXAMPLE 1

This example illustrates the superior inter-particle homogeneity of the in-situ blends produced by the bimetallic catalyst over that of the tandem reactor resins.

30 Presently, commercial samples of HDPE with a bimodal MWD are produced in a tandem reactor process. In that process, two reactors are run in series and the catalyst is exposed to ethylene polymerization conditions in one reactor, and the resulting polymer-catalyst particles are transferred to a second 35 reactor for additional polymerization. One of the main process differences in the two different reactors, is that the amount of hydrogen is different in the two different reactors.

- 23 -

Relatively lower molecular weight product is produced in the reactor containing more hydrogen, because the hydrogen acts as a chain transfer agent; whereas relatively higher molecular weight product is produced in the reactor containing lesser 5 relative amounts of hydrogen.

The reactor samples were sieved to segregate them as a function of particle size. The individual sieved fractions were analyzed by GPC to determine their molecular weight distribution. The results are tabulated below:

10

	<u>Resin</u>	<u>Mw*</u>	<u>Mw/Mn**</u>
<u>Tandem Reactor Process****</u>			
	#18 sieve	277600	18.30
	#60 sieve	236000	18.9
15	#120 sieve	222700	18.0
	#170 sieve	196000	17.8
<u>Bimetallic Catalyst C-2***</u>			
	#18 sieve	276800	35.8
20	#35 sieve	269200	33.6
	#60 sieve	290700	32.7
	#120 sieve	267400	33.0
	#200 sieve	285200	37.5

25 *Mw is weight average molecular weight measured by GPC.

**Mn is number average molecular weight measured by GPC.

***Catalyst C-2 (above)

****This process used a catalyst which was a silica-supported Ti/Mg complex which was not pre-reduced or partially activated 30 with tri-n-hexylaluminum. The catalyst precursor contained 1.13 wt.% Ti, 1.95 wt.% Mg, 8.22 wt.% Cl, 15.4 wt.% THF, and 1.41 wt.% Al.

The particles of product are characterized by weight average particle diameter ranging from 0.01 inches to 0.04 35 inches (0.25 to 1 mm), but preferably range from 0.015 to 0.022 inches (0.38 to 0.56 mm).

For the bimetallic catalyst resin particles, the Mw of the

- 24 -

highest molecular weight sieved fraction is only 8.7 percent higher than the M_w of the lowest molecular weight fraction. On the other hand, for the tandem resin, the highest molecular weight fraction has a M_w which is 41.6 percent higher than the 5 M_w of the lowest molecular weight fraction. In addition, unlike the bimetallic resins, the molecular weight of the tandem resin fractions decreases with decreasing particle size. Thus, the tandem resin particles are more heterogeneous than the corresponding bimetallic (Ti/Zr) catalyzed resin particles.

10 The differences in the heterogeneity of the two bimodal products is also reflected in the appearance of the films produced from these resins. The film quality rating (FQR) of the Ti/Zr film was 10 while the tandem resin film sample had a FQR of 50. The higher FQR denotes higher gel levels and thus 15 poorer film appearance. The low FQR of the Ti/Zr film is truly impressive considering the fact that it has a significantly broader MWD (M_w/M_n of 36 versus 18) with more distinct bimodality.

20 Particle heterogeneity of the bimodal HMW-HDPE resin produced the Ti/Zr catalyst (of US-A-5032562) with the MAO cofed externally. The MWD was characterised of the individual sieved fractions of a sample which would be similar to the one described in Example 4 of that patent. The results are as follows:

25

	<u>Sieve #</u>	<u>M_w</u>	<u>M_w/M_n</u>
	18	327811	8.17
	60	242030	14.49
	120	97412	12.88
30	200	77986	10.52
	pan(>200 sieve)	11907	1.8

35 This analysis shows that the particles made by the MAO cofeed process are very heterogeneous. In Example 1, the resin made from a Ti/Zr containing the preactivated Zr had only a 9 percent difference between the M_w of the lowest molecular weight fraction and the M_w of the highest molecular weight fraction.

- 25 -

In contrast, the result with product of US-A-5032562 shows that the M_w of the highest molecular weight fraction is almost 30 times the M_w of the lowest molecular weight fraction. Also, there is a wide variation in the M_w/M_n of the fractions: 1.8-
5 14.49.

Example 2

This example demonstrates the broad range of products that are possible with the Ti/Zr catalyst system. By proper
10 selection of the catalyst formulation and reactor conditions, we were able to produce resins covering a broad range of FI, MFR and density. These resins also represented a broad range of component weight fractions and molecular weights (FI, MI). The following equations illustrate the versatility of the
15 technology:

1. $Den = 0.944 + 0.19(H_2/C_2) - 0.25(C_6/C_2) + 0.00027(T 90) + 0.0063(\log_{10}FI)$

T-value	1.9	7.1	3.1
---------	-----	-----	-----

R square = 89

2. $\ln FI - HMW = -1.6 + 75(H_2/C_2) + 0.063(T-90)$

T-value	7.3	6.8
---------	-----	-----

R square = 92

3. $\ln MI - LMW = 7.5 + 166(H_2/C_2) - 41(C_6/C_2) + 0.03(T-90)$

T-value	11.9	10.3	1.8
---------	------	------	-----

R square = 98

25 4. $XHMW = 0.979 - 2.2(H_2/C_2) - 2.4(C_6/C_2) + 0.008(T-90) - 0.039(PZ^*)$

T-value	2.3	6.1	4.4	4.3
---------	-----	-----	-----	-----

R square = 96

* $PZ = \text{mmol (Al)}/\text{g precursor}$; at an Al/Zr ratio of 100.

Using the appropriate control variables, it is possible to
30 make resins with a HMW weight fraction range of .1-.8, a HMW FI range of .01 to 4 and a LMW MI range of 20 to 20,000.

A brief description of the mathematical technique that is used to estimate the composition (Molecular weight and weight fraction) of the bimodal molecular weight distribution produced
35 by the bimetallic catalyst appears in Computer Applications in Applied Polymer Science, ACS Symposium Series, 197, T. Provder, 45, 1982.

- 26 -

Example 3

In this example, we compare the level of unsaturation encountered in the Ti/Zr resin with that of typical tandem resin. These measurements were made on granular resins with 5 standard FTIR spectroscopy techniques.

<u>Sample</u>	<u>Total Unsaturation Level, per 1000 carbons</u>
Ti/Zr	0.92
10 Tandem	0.18

Example 4

This example illustrates the narrow MWD of the LMW component in the bimodal product produced by the Ti/Zr catalyst. 15 The attached GPC curve clearly shows (by its relative sharpness) that the LMW peak for the bimodal Ti/Zr resin is significantly narrower in MWD when compared to the LMW MWD of a typical tandem resin. The MWD of the LMW component in the Ti/Zr catalyzed resin is expected to be narrower in distribution because it is 20 made by the Zr catalyst component. The metallocene Zr catalyst is known to produce resins with substantially narrower MWD compared to a typical Ziegler Natta based Ti catalyst. The latter are used in producing both the HMW and LMW components in the tandem process. The MWD of the LMW component can also be 25 deduced by deconvoluting the bimodal GPC curve into its component. With this technique, the molecular weights and molecular weight distribution of each component can be estimated. This technique also shows the LMW component to be narrower in MWD for the Ti/Zr catalyzed resins. The LMW 30 component in Ti/Zr catalyzed resins has Mw/Mn range of 2-3.5, while the LMW component in a typical tandem resin has Mw/Mn range of 4-6.

While the invention has been described in conjunction with specific embodiments thereof, it is evident that many 35 alternatives, modifications, and variations, within the scope of the claims, will be apparent to those skilled in the art in light of the foregoing description.

Claims

1. A resin composition comprising a polymer of ethylene, copolymer of ethylene or a mixture thereof, the resin having a 5 density of 0.89 to 0.97; has a M_w/M_n of 2.5 to 60, and has a FI of 1 to 100, wherein said resin comprises a blend of 2 components of different, molecular weight wherein one of said two components is a high molecular weight component (HMW) and wherein another of said two components is a low molecular weight 10 component (LMW) with a molecular weight less than that of HMW, the HMW component having a FI of 0.005 to 50 and the LMW component having a MI of 0.1 to 20,000 and a M_w/M_n of 2 to 30, and wherein the M_w and the M_w/M_n of said blend in said particles is substantially constant over said range of weight average 15 particle diameter.

2. A resin according to Claim 1, in the form of particles having a weight average particle diameter in the range 0.01 to 0.04 inches (0.25 to 1 mm).

20

3. A resin according to Claim 1 or 2, which has a density which ranges from 0.930 to 0.970 g/cc.

4. A resin according to Claim 1 or 2, which has a specific 25 density which ranges from 0.940 to 0.970.

5. A resin according to Claim 1 or 2, which has a specific density which ranges from 0.930 to 0.940.

30 6. A resin according to Claim 1 or 2, wherein the M_w/M_n ranges from 10 to 40.

7. A resin according to Claim 1 or 2, wherein the M_w/M_n ranges from 15 to 30.

35

8. A resin according to Claim 1 or 2, wherein the polymer or copolymer has a total unsaturation measured by IR which ranges

- 28 -

from 0.1 to 3.0 per 1000 carbon atoms.

9. A resin according to Claim 1 or 2, which is crosslinkable.

5 10. A resin according to Claim 1 or 2, wherein the molecular weight distribution M_w/M_n of the LMW fraction ranges from 2 to 5.

11. A resin according to Claim 1 or 2, wherein the molecular weight distribution M_w/M_n of the LMW fraction ranges from 2 to 10 3.5.

12. A resin according to Claim 1 or 2, wherein the molecular weight distribution M_w/M_n of the LMW fraction ranges from 2 to 15 2.5.

13. A resin according to Claim 1 or 2, which is a homopolymer of ethylene.

20 14. A resin according to Claim 1 or 2, which is a copolymer of ethylene and an alpha olefin of 3 to 10 carbon atoms.

15. A resin according to Claim 1 or 2, which is a copolymer of ethylene and an alpha olefin of 4 to 8 carbon atoms.

25 16. A resin according to Claim 1 or 2, which is a copolymer of ethylene and an alpha olefin which is selected from the group consisting of propylene, 1-butene, 1-hexene, 1-octene, 4-methyl-pentene and admixtures thereof.

30 17. A resin according to Claim 1 or 2, which is a copolymer of ethylene and 1-hexene.

18. A resin according to Claim 13, wherein the copolymer 35 comprises 0 to 20 weight percent of alpha olefin.

19. A resin according to Claim 1 or 2, wherein the resin

- 29 -

contains 0.1 to 10 ppm of metallocene transition metal.

20. A resin according to Claim 18, wherein the resin contains 1 to 30 ppm titanium.

5

21. A resin according to Claim 1 or 2, wherin the resin has a specific density in the range of 0.918 to 0.929.

22. A process for preparing a resin according to claim 1,
10 comprising polymerizing ethylene or ethylene and another olefinic material in a single reactor in the presence of a catalyst comprising a metallocene transition metal.

23. A process according to Claim 22, wherein the catalyst
15 further comprises a non-metallocene transition metal containing compound.

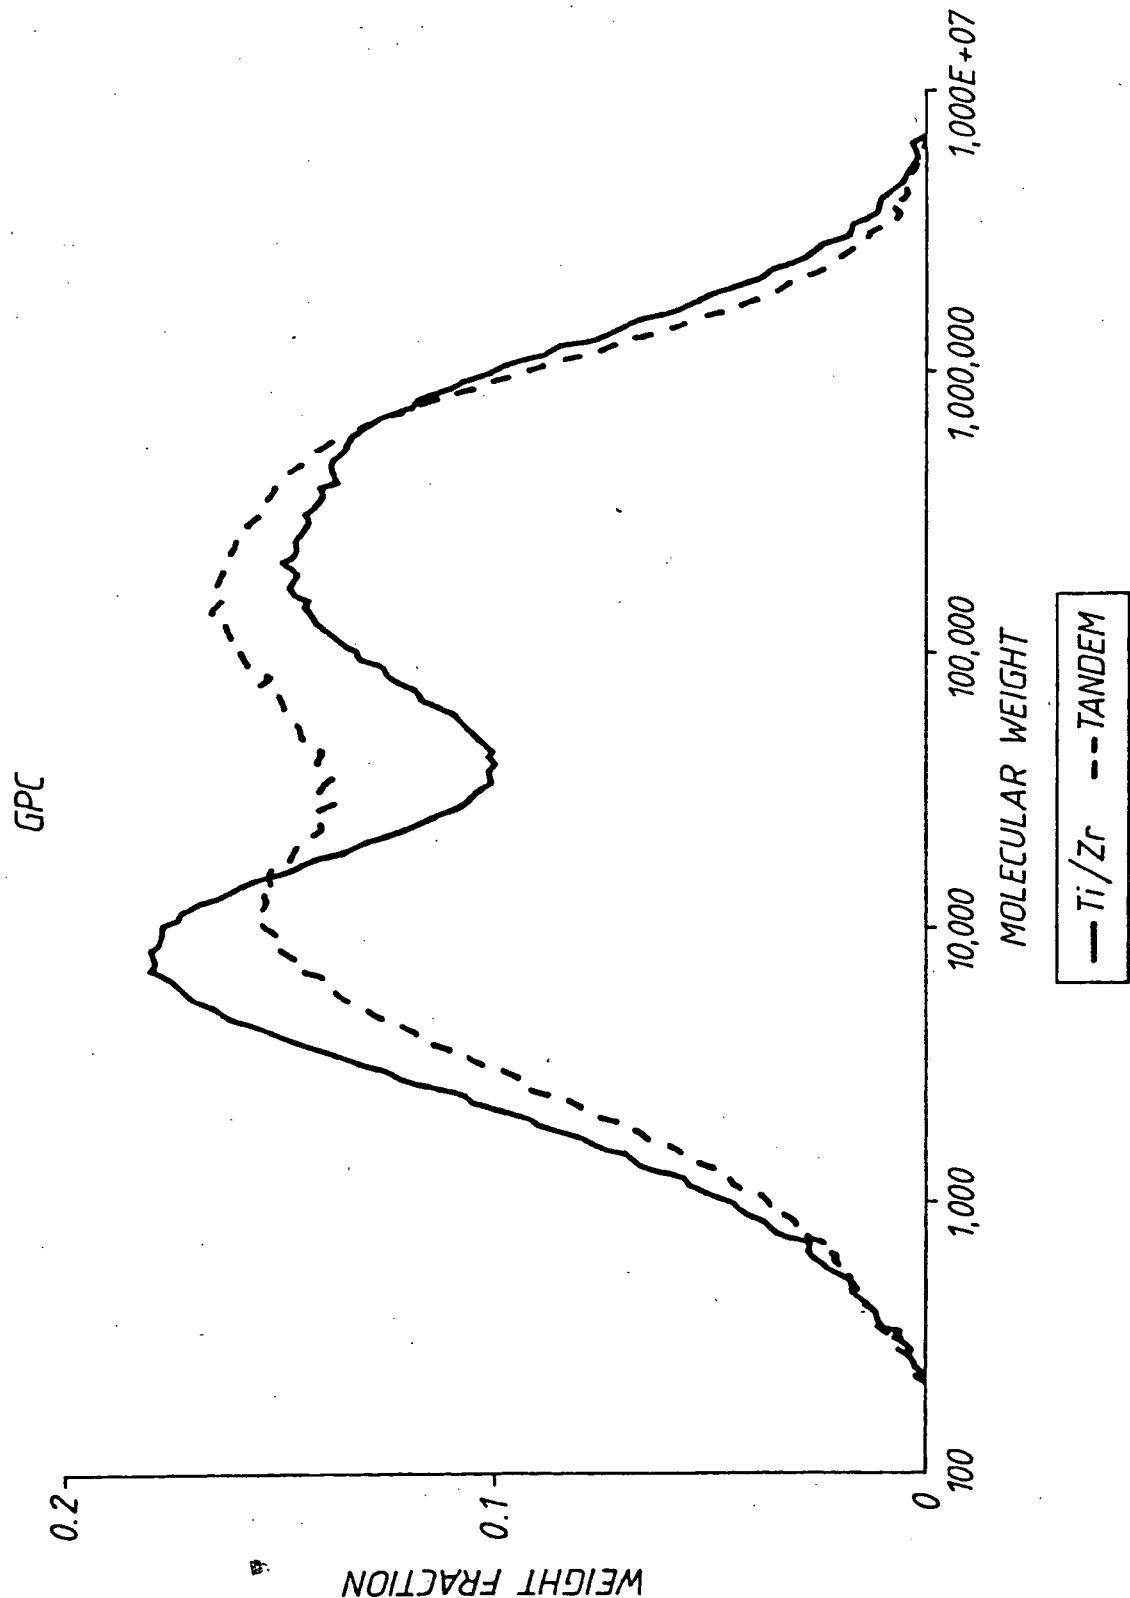

24. A process according to Claim 22 or 23, wherein the catalyst further comprises an aluminum alkyl compound as a cocatalyst.

20

25. A film formed from the resin according to Claim 1.

26. An article blow molded from the resin according to Claim 1.

US CL :525/240, 247, 270; 526/114, 119

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 525/240, 247, 270; 526/114, 119

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US, A, 5,077,255 (WELBORN, JR.) 31 December 1991, column 3, lines 40-52; column 10, lines 6-39, Example 2.	1-26
--		-----
Y		1-26
X	US, A, 5,032,562 (LO ET AL.) 16 July 1991, column 9, lines 38-64; Examples 1-4.	1-26
--		-----
Y		1-26

Further documents are listed in the continuation of Box C.

See patent family annex.

Special categories of cited documents:	
A	document defining the general state of the art which is not considered to be part of particular relevance
E	earlier document published on or after the international filing date
L	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
O	document referring to an oral disclosure, use, exhibition or other means
P	document published prior to the international filing date but later than the priority date claimed
	T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
	X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
	Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
	& document member of the same patent family

Date of the actual completion of the international search

22 NOVEMBER 1994

Date of mailing of the international search report

20 DEC 1994
